

## A. Describe Your Objects

For my product website, I plan to create a JavaScript object that represents a customer booking for a haircut appointment. This object will store important details such as the customer's name, the service they chose, the day and time of their appointment, and whether they selected add-ons like a beard trim or applied a discount. These details will be stored as properties inside the object. The object will also include methods, such as one that calculates the total price based on the selected service and add-ons, and another that formats a confirmation message for the user. I need these properties and methods because they match the actions users take on the site—choosing a service, selecting options, and booking a time—while the methods allow the site to automatically compute pricing and generate feedback without rewriting the same code in multiple places.

## B. Draw Your Object Model
